## Programming Challenge: Variables and Constants

### Using Constants for a Tax Calculation (HARD)

[https://isaacomputerscience.org/questions/varconst\\_hard](https://isaacomputerscience.org/questions/varconst_hard)

- Write a Python program that calculates the total price of an item using a constant tax rate.
- The price before tax is stored in a variable, and a constant value is used for the tax rate.
- The program should calculate the total price by adding the tax to the original price.

You need to:

1. Declare and initialise a variable for the price of the item.
2. Use a constant for the tax rate (e.g. 20%).
3. Calculate the total price including tax.
4. Display the result.

### Example Output:

The total price including tax is 60.
